Abstract

Leverage is one of the important component of capital structure. It is magnifying force or power, which is employed to achieve more output. In financial management it refers to investment in fix assets and designing of capital structure of a firm in such as way so that fixed costs are present. It may be defined as use of fixed charge securities in capitalization of company. Leverage not only tends to magnify shareholder's return under favorable conditions but also exposes to financial risk because the use of debt increases variability in shareholders return and profitability This paper is focused on impact of financial leverage on return of private sector companies in India after liberalization. Main objective of this paper is to measure the impact of financial leverage return of private sector companies during the period of post liberalization. Research is based on secondary data, which is collected from prowwess and annual reports of the companies.

Keywords: Financial Leverage, Liberalization, Return, Risk, Capital Structure.

Introduction

Financial leverage is the final component of return on equity. It is a measure how much firm uses equity and debt to finance its assets. As debt increases , financial leverage increases and the Management tends to prefer equity financing over debt since it carries less risk. It is calculated by dividing assets by shareholder equity (Matt, 2000). When the surplus increases and deficit decreases, the return on the owners' equity, referred to as a double-edged sword, financial leverage provides the potentials of increasing the shareholders' wealth as well as creating the risks of loss to them. It is a prerequisite for achieving optimal capital structure. An optimal capital structure can influence the value of firm and wealth of shareholder's through reduced cost of capital. Hence, determination of optimal debt level and its impact on the firm's over all capital structure is regarded as an integral part of a firm's financial decision (Franklin and Muthusamy, 2011). Financial leverage, or an increase in financial efficiency, called the variation of return on equity, depends on the return on assets and the cost of credit i.e., interest rate. It also expresses the impact of financial expenses due to loans on the return on equity of an enterprise (Brezeanu, 1999). Return can be defined to change value of an asset during a specified time period. This change is due to the price change plus interest or payments benefits. In other words, the return on investment in the common stock is achieved at a certain period according to price of the first and last time and benefits of ownership. Economically, the purpose of people from buying shares of companies and businesses is to obtain efficiency (karami, 2001).

Review of Literature

Banz (1980) has examine the relationship between return and total market value of NYSE common stocks. He found that the smaller firms have had high risk adjusted returns, on average, than larger firms. karami, (2001) defines the return on investment in the common stock is achieved at a certain period according to price of the first and last time and benefits of ownership. Yoon and Cheong (2003) did the work on the effect of financial leverages on profitability and risk of restaurants firms. The research result suggest that the during the period at least firm size had more dominate effect on ROE of restaurant firms than debt use, larger firm earnings significantly higher equity return. Henry (2003) has analyzed the

impact of equity market liberalization upon cost of capital. He stated that equity market liberalization was specific type of capital account liberalization, which was a decision to allow capital in all forms to move freely in and out domestic market. Gritta, Adams, and Adrangi (2004) have done work on the topic an analysis of the effects of operating and financial leverage on major U.S. air carriers rate of Return. Hovey (2005) has done the research work on Leverage, Profitability and the ownership structures of listed firms in china. He described the relationship between leverage, profitability and a firm's ownership structure in china. Chanderakumarmanglam and Govindasamy (2010) has done the work on leverage- an analysis and its impact on profitability to selected cement companies in India Adami, Gough, Murodoglu and Sirparsad (2010) has done the work on leverage effect on stock return, The source of all data is Thomson Reuters DataStream They examined the relation between abnormal stock returns and leverage. The findings indicate that returns are decreasing in firms leverage. tests this relation empirically with other risk factors and finds that the results remain robust. Singapurwoko and Mustafa (2011) has done the work on the impact of financial leverages to profitability study of non financial companies listed in Indonesia stock exchange. Main objective of the study was to know the impact of financial leverage to profitability. Rafique (2011) has investigated the effect of the profitability of the firm and its financial leverage on the capital structure of the automobile sector in Pakistan. Saleem and Naseem (2011) has analyzed the leverage and profitability of selected oil and gas companies of Pakistan The result also indicated that high levered firms were less risky in both market based and accounting based measured. Pachori and Totala (2012) did the work on influence of financial leverages on shareholders return and market capitalization: A study of automotive cluster companies of Pitahmpur MP India .Saini (2012) has done the research impact of financial leverage on shareholders return and market. Shabahang, (2012) examines the Rate of return on the investment portfolio is a set weighted average of return capitalization; An empirical evidence of telecommunication n sector companies in India. Singh (2013) has done on the work capital structure practices in Indian corporate sector. The main objectives of the study were to study existing capital structure practices in Indian corporate sector, to examine the impact of the capital structure decisions on cost of capital and to find out the leverage effect on earnings per share and market price per share. He found that capital structure positively related to MPS in traditional and combined data whereas negative in case modern industries. Muhammad, Ahmad, Rabia and; Khalil-Ur-Rehman (2015) has done the work on effect of leverage on financial health of the firm- A study of cement industry in Pakistan. They tried to measure the relationship between leverage and profitability of firms in the cement industry of Pakistan. Debt to equity is used to measure the leverage of the companies in the cement industry in Pakistan.The of the study shows negative and significant relationship

between leverage and profitability of the firm. Rudin , Djayani and ; Vita Yanti Fattah (2016) , has done the work on the topic , The effect of liquidity and leverage on profitability on property and real estate company on Indonesian stock exchange. Their result showed that the leverage and liquidity simultaneously have significant effect on profitability, liquidity have an effect partially on profitability, but the effect was not significant, leverage have a significant effect on profitability partially.

Objectives of Study

To measure the impact of leverage on return private sectors companies during the period of post liberalization

Research Methodology and Financial Tool

The present research is based on secondary data .In order to achieve the objective, a sample of 25 private sector companies has been obtained from annual reports of the different companies, PROWESS, Official directory of Bombay Stock Exchange etc. For the purpose of data analysis, a panel data analysis has been used. The reference period of study for post liberalization is 2000 to 2012.

Leverage (Financial Leverage).

Leverage analysis is the is technique, which is used to quantify risk and return relationship of different alternatives of capital structure. it refers to percentage of assets financed by debt. It is exposure of financial risk. A high level of financial leverage allowed the shareholders to obtain high return on equity , but exposed to higher significant of loss , if return on assets is lower, C.A Sachdanand Pachori and Dr Davindr Totla (2012).

- Leverage 1= Total debt/ Total assets
- Leverage 2= short term debt/equity
- Leverage 3= Debt/ equity
- Leverage4= long term debt /equity

Limitation of Research

It is based on secondary data and limited to availability of annual reports companies. Thus, the conclusion drawn are subject to correctness of data.

Analysis

1. Impact of Leverage on Return of Private Sector Companies during the period of Post Liberlization
2. Impact of Leverage On Return (ROA) of Private Sector Companies during the period of Post Liberlization

VIF table 6.1 shows value of all independent variable are below 3, of effect of leverage on return of private sector companies during the period of post liberalization, so multi collinearly cannot be problem for this model.

Table 6.1 VIF Table of Private Sector Companies for Leverage1 Post Liberalization

Variable	VIF	1/VIF
FS	2.72	0.367051
EBIT	2.22	0.450337

Table 6.3 shows the result of random effect regression of private sector companies after liberalization. The value of Wald chi-square test is 100.51 with p value 0.0000, less than .05, hence

indicates data is statistically suitable for interpretation. The value of R square (overall) is 0.3649 , which indicates that model has explained 36.49 percent of variation in return. The empirical results shows that leverage measured by total debt to total assets have negative relation with return and relation have found statistically significant at one percent level.

The Hausman's test result in table 6.5 shows value of chi square is 7.55 with p value 0.2733 , which is more than .05 level, hence does not support the null hypothesis and indicates random effect model is suitable for interpretation. Table 6.6 indicates value of Wald chi square test is 43.97 with p value 0.0000, which is less than .05 level hence support the goodness of fit for this modal. The R square value (overall) is 0.1080 which means 10.80 percent variation in return has been explained by this model.

The R Square value(within) is 0.1474, which means 14.75 percent of variation to be expected in return has been explained by this model. The empirical result shows that leverage measured by total debt to total assets has positive impact on return and has been found statistically significant. From the control variables firm size, current ratio and non debt tax shield found positive and significant relation with return, whereas remaining variables has been found positive and statistically insignificant relation with return.

The variation inflation factor test value in table 6.16 are below 3, hence multi co linearity cannot be problem for given variables.

The Hausman's chi square test value in table 6.17 is 21.23 with p value 0.0017, which is less than .05 level, hence reject null hypothesis difference in coefficient is not systematic, recommend fixed effect model is suitable for data interpretation.

The result of fixed effect regression has been shown in table 6.18. the value of F statistic is 7.58 with p value, 0.0000, which is less than .01 level,

small enough to reject null hypothesis, therefore model has been statistically significant and fit for interpretation. The R square value (within) is 0.1534, which indicates 15.34 percent of variation in return has been explained by this model.

The empirical results shows that leverage measured by short term debt to total asset has negative relation with return and statistically significant .The control variables firm size, have found positive and statistically significant relation with return and current ratio and non debt tax shield negative and significant relation with return. Whereas other control variables have been found positive and insignificant relation.

Table 6.19 shows the result of VIF test value, which are below 3, hence indicate the absence of severe co linearity .

The result of fixed effect regression has been shown in table 6.21 which shows F statistics value 6.55 with p value 0.000.The R square value (within) is 13.53 , which indicates 13.53 percent of variation in return has been explained by this model. The empirical results shows that leverage measured by

total debt to equity has positive and insignificant relation with return. From the control variables firm size, current ratio and tangibility has been found positive and statistically significant relation with return whereas tangibility, earnings before interest and taxes and growth have positive and insignificant relation other remaining control variables has been found negative and insignificant relation with return.

From the other control variables firm size have found positive and significant relation with return, whereas current ratio and non debt tax shield has been negative and significant relation and remaining other variables has been found positive and insignificant relation with return.

Conclusion

The result of objective to measure the impact of leverage on return private sectors companies during the period of post liberalization shows that In case return measured by ROA in case of private sector companies during the period of post

is less than .05 level , hence reject null hypothesis , difference in coefficient is not systematic , hence recommended fixed effect modal is suitable for data interpretation.

is 0.1356, which indicates 13.56 percent of variation in return has been explained by this model. The empirical result shows that leverage measured by long term debt to equity has positive relation with return and has been found statistically insignificant.

liberalization shows only leverage 1 (total debt/ total assets) have significant relation with return. However in case of non debt tax shield have significant and positive relation with leverage 1, leverage2 and leverage 3 and leverage4 and significant and negative relation with tangibility. leverage2, leverage3 and leverage4 shows positive and significant relation firm size whereas leverage 1 shows positive and significant relation with earnings before interest and taxes. However in case return measured by ROE private sector companies during the period of post liberalization shows only leverage 1(total debt/ total assets),leverage2(short term debt /equity) have significant positive relation with return. It also shows

that leverage1, leverage2 and leverage 3 and leverage4 and significant positive relation with firm size .However in case of current ratio and non debt tax shield have significant and positive relation with leverage 1 and significant negative relation with leverage2 and leverage 3 and leverage4.
