## Abstract

Temperature of a region can be treated as a vector time series. In this article, we have
treated temperature of Marathwada of Maharastra state as a vector $\bar{t}=\left(X_{1}, X_{2}, \ldots X_{5}\right)$. Where $X_{1}=$ temperature at Aurangabad, $X_{2}=$ temperature at Parbhani, $X_{3}=$ temperature at Osmanabad, $X_{4}=$ temperature at Beed and $\mathrm{X}_{5}=$ temperature at Nanded. Thus, we get a vector time series, $\overline{\mathrm{T}}=\left(\mathrm{t}_{\mathrm{i}} \mathrm{j}\right)$, $\mathrm{i}=1,2, \ldots \mathrm{n}$ years, $\mathrm{j}=1,2 \ldots 5$ districts(districts having five temperature stations). This opens up very interesting questions. How are the properties of $T$ related to component time series?.

A preliminary discussion of properties of vector time series and possible testing methodology for trend property precedes the actual application to regional temperature data.

Keywords: Time Series, Vector Time Series, Regression Analysis, Auto Covariance Function, Auto-Correlation Function.

## Introduction

Vector time series can occur naturally in real life. For example, if we consider the temperature over a region, where temperature is recorded over a cluster of recording stations, we get a vector temperature time series. To what extent the properties of component time series determine the properties of the regional vector time series is worth looking into.

In what follows are first discussed in relation to, few properties of vector time series and then tried to compute the same for the regional annual 33 years temperature record of Marathwada region by using data from 1970 to 2002.

## Basic Concepts

Basic definitions and few properties of vector stationary time series are given in this section.

## Definition 2.1: A Random Vector

A random vector, $\bar{X}=\left(X_{1}, X_{2}, \ldots X_{k}\right)$ is a single valued function whose domain is $\Omega$, whose range is in Euclidean $n$-space $R^{n}$ and which is B-measurable, i.e. for every subset $R \subset R^{n}\left\{\omega \in \Omega \mid X_{1}(\omega) \ldots X_{k}(\omega) \epsilon\right.$ $R\} \in B$. A random vector will also be called an K - dimensional random variable or a vector random variable.

If $X_{1}, X_{2} \ldots X_{k}$ are $k$ random variables and $\bar{X}=\left(X_{1}, X_{2} \ldots X_{k}\right)$ is a random vector, [15].

## Definition 2.2: A Vector Time Series

Let ( $\Omega, \mathrm{C}, \mathrm{P}$ ) be a probability space; with $\Omega$ sample space; $\mathrm{C}=$ $\sigma(\Omega)$. Let T be an index set and $\mathrm{N}=\{1,2 \ldots \mathrm{k}\}$. A real valued vector time series is a real valued function $X_{i t}(\omega), i=1,2 \ldots k$ defined on $N \times T \times \Omega$ such that for each fixed $t \in T, i \in N, X_{i t}(\omega)$ is a random variable on ( $\Omega, C, P$ ).

A vector time series can be considered as a collection $\left\{X_{i t}: t \in T\right\}$, $=1,2 \ldots \mathrm{k}$ of random variables [16].

## Definition 2.3: Stationary Vector Time Series

A process whose probability structure does not change with time is called stationary. Broadly speaking a vector time series is said to be stationary, if there is no systematic change in mean i.e. no trend. There is no systematic change in variance.

Let $\bar{X}=\left(x_{1}, x_{2} \ldots x_{n}\right)$ be realizations of random variables $\left(X_{1}, X_{2} \ldots\right.$ $X_{K}$ ).

## Definition 2.4: Strictly Stationary Vector Time Series

A vector time series is called strictly stationary, if their joint distribution function satisfy

# 05/INNO/ 3/2020/12181 

$$
F_{x_{1 t}}\left(\bar{x}_{X_{2 t}} \ldots \bar{x}_{k t} F(\bar{x}) x_{1 t+h} x_{2 t+h} \ldots \dddot{x}_{k t+h}\right.
$$

Where, the equality must hold for all possible sets of indices (it) and (it +h ) in the index set. Further the joint distribution depends only on the distance $h$ between the elements in the index set and not on their actual values.

## Main Results

Theorm 3.1: If $\left\{X_{i t}: t \in T\right\}, i=1,2, \ldots k$ is strictly vector time series with $E\left\{X_{i t}\right\}<\alpha$ and

$$
E\left\{X_{i t}-\mu\right\}<\beta \text { then, }
$$

$$
E\left\{X_{i t}\right\}=E\left\{X_{i t+h}\right\}, \text { for all it, } h
$$

and $\quad E\left[\left\{X_{i t}-\mu_{i}\right\}\left\{X_{j t}-\mu_{j}\right\}\right]=E\left[\left\{X_{i t+h}-\mu_{i}\right.\right.$ $\left.\}\left\{X_{j t+h}-\mu_{j}\right\}\right]$, for all it, $\left.h \quad\right\} \ldots$ (2)
Proof : Proof follows from definition (2.4).
In usual cases above equation (2) is used to determine that a vector time series is stationary.
Definition 3.1: Weakly stationary vector time series

A vector time series is called weakly stationary if

1. The expected value of $X_{i t}$ is a constant for all it.
2. The covariance matrix of $\left(X_{1 t}, X_{2 t}, \ldots X_{k t}\right)$ is same as covariance matrix of

$$
\left(X_{1 t+h}, X_{2 t+h} \ldots X_{k t+h}\right)
$$

A look in the covariance matrix $\left(X_{1 t} X_{2 t} \ldots X_{k t}\right)$ would show that diagonal terms would contain terms covariance ( $X_{i t}, X_{i t}$ ) which are essentially variances and off diagonal terms would contains terms like covariance $\left(X_{i t}, X_{j t}\right)$. Hence, the definitions to follow assume importance. Since these involve elements from the same set $\left\{X_{i t}\right\}$, the variances and co- variances are called autovariances and auto-co variances .
Definition 3.2: Auto-covariance function: The covariance between $\left\{X_{i t}\right\}$ and $\left\{X_{i t+h}\right\}$ separated by $h$ time unit is called auto-covariance at lag h and is denoted by $\Gamma_{i j}(h)$.
$\Gamma_{i j}(h)=\operatorname{cov}\left(X_{i t}, X_{j t+h}\right)=E\left\{X_{i t}-\mu_{i j}\left\{X_{j t+h}-\mu_{j}\right\}\right.$ ... (3)
The matrix $\Gamma \bar{h}=\Gamma_{i j}(h)$ is called the auto covariance matrix function.

## Definition 3.3: The Auto Correlation Function

The correlation between observation which are separated by h time unit is called auto-correlation at lag h . It is given by

$$
\begin{array}{r}
P_{i j}(h)=\frac{E\left\{X_{i t}-\mu_{i j}\left\{X_{j t+h}-\mu_{j}\right\}\right.}{\left[E\left\{X_{i t}-\mu_{i j}\right\}^{2} E\left\{X_{j t+h}-\mu_{j}\right\}^{2}\right]}{ }^{1 / 2}  \tag{4}\\
=\frac{\Gamma_{i j}(h)}{\left[\Gamma_{i i}(h) \Gamma_{j j}(h)\right]^{1 / 2}}
\end{array}
$$

Where, $\mu_{i}$ is the mean of $i^{\text {th }}$ component time series.

## Remark 3.1

For a vector stationary time series the variance at time (it +h ) is same as that at time it. Thus, the auto correlation at lag $h$ is
$\mathrm{P}_{\mathrm{ij}}(\mathrm{h})=\frac{\Gamma \mathrm{ij}(\mathrm{h})}{\Gamma \mathrm{ii}(0)}$
Remark 3.2
For $h=0$, we get $\rho_{i j}(0)=1$.
For application attempts have been made to establish that temprature at certain districts of Marathwada satisfy equation (1) and (5).

## Definition 3.4: Positive Semi-Definite

A function $f(x)$ defined for $x \in X$ is said to be positive semi-definite if it satisfies

$$
\sum_{J=i}^{n} \sum_{k=1}^{n} a_{k}^{\top} f\left(t_{j}-t_{k}\right) a_{j} \geq 0
$$

For any set of real vectors ( $a_{1}, a_{2}, \ldots a_{n}$ ) and any set of indices $\left(\mathrm{t}_{1}, \mathrm{t}_{2} \ldots \mathrm{t}_{\mathrm{n}}\right) \in \mathrm{T}$ such that

$$
\left(t_{j}-t_{k}\right) \in X .
$$

## Theorem 3.2

The covariance function of vector stationary time series $\left\{\mathrm{X}_{\mathrm{it}}: \mathrm{t} \in \mathrm{T}\right\}$ is positive semi-definite function in that

$$
\sum_{j=1}^{n} \sum_{k=1}^{n} a_{k}{ }^{\top} \Gamma\left(t_{j}-t_{k}\right) a_{j} \geq 0,
$$

For any set of real vectors ( $a_{1}, a_{2}, \ldots a_{n}$ ) and any set of indices $\left(\mathrm{t}_{1}, \mathrm{t}_{2} \ldots \mathrm{t}_{\mathrm{n}}\right) \in \mathrm{T}$.
Proof: The result can be obtained by evaluating the variance of

$$
X=\sum_{j=1}^{n} a j^{\top} X_{t j} .
$$

For this without loss of generality $E\left(X_{t j}\right)=0$. It shows that the variance of a random variable is non-negative i.e. $V(X) \geq 0$.

$$
\begin{align*}
& \geq U(X)=V\left(\Sigma a_{j}{ }^{\top} X_{t j}\right) \geq 0 \\
= & E\left(\sum_{j=1}^{n} a j^{\top} X_{t j}\right)\left(\sum_{k=1}^{\top} a_{j}^{n} j^{\top} X_{t j}\right) \geq 0, \\
= & \sum_{j=1}^{n} \sum_{k=1}^{n} a_{j}^{\top} a_{k} E\left\{X_{t j} X_{t k}\right) \geq 0, \\
= & \sum_{j=1}^{n} \sum_{k=1}^{n} a_{k}^{\top} \Gamma\left(t_{j-t} t_{k}\right) a_{j} \geq 0 \quad \ldots \tag{6}
\end{align*}
$$

Theorem 3.3: $\left|\rho_{12}(\mathbf{h})\right| \leq 1$.
Proof: If we set $\mathrm{n}=2$, in the equation (6) to obtain,

$$
\begin{aligned}
& \sum_{22}(0)+2 a_{i=1}^{n} \sum_{i=1}^{n} \sum_{j=1}^{n} a_{t_{1}-t_{2}}^{\top} \Gamma_{2}^{\top} \geq 0 . \\
& \left.a_{i} t_{i-} t_{j}\right) a_{i}=a_{1}^{2} \Gamma_{11}(0)+a_{2}^{2} \\
& \text { since } \Gamma_{11}(0)=\Gamma_{22}(0)+a_{2}^{2} \Gamma_{22}(0) \geq-2 a_{1} a_{2}^{\top} \Gamma_{12}\left(t_{1}-t_{2}\right),
\end{aligned}
$$

$$
\begin{gathered}
1 / 2\left(a_{1}^{2}+a_{2}^{2}\right) \quad \stackrel{-a_{1} a_{2}^{\top} \Gamma_{12}\left(t_{1}-t_{2}\right)}{\Gamma_{11}^{(0)}} \\
\text { Now, let } a_{1}=a_{2}=1 \text { and } t_{1}-t_{2}=h,
\end{gathered}
$$

## 05/INNO/ 3/2020/12181

$$
\begin{equation*}
1 \geq \frac{-\Gamma 12(\mathrm{~h})}{\Gamma_{11}(0)}=-\rho_{12}(\mathrm{~h}) \tag{7}
\end{equation*}
$$

Similarly, $-a_{1}=a_{2}=1$; it shows that $P_{12}(h) \leq 1$
From (7) and (8) we get
$\left|\rho_{12}(h)\right| \leq 1$.
Hence proved.
Theorem 3.4
The auto covariance matrix of vector stationary time series is an even
function of h. i.e., $\Gamma_{i j}(h)=\Gamma_{i j}(-h)^{\top}$.
Proof: Here,

$$
\operatorname{Cov}\left(X_{i}, Y_{i+1}\right)=\left\{\Sigma X_{i} Y_{i+1}-1 / n \Sigma X_{i} \Sigma Y_{i}\right\} / n
$$

If $X_{i}, Y_{i}$ are different series.
$\operatorname{Cov}\left(X_{i}, Y_{i+1}\right) \neq \operatorname{Cov}\left(X_{i}, Y_{i-1}\right)$
i.e. $\left\{\Sigma X_{i} Y_{i+1}-1 / n \Sigma X_{i} \Sigma Y_{i}\right\} / n \neq\left\{\Sigma X_{i} Y_{i-1}-1 / n \Sigma X_{i}\right.$ $\left.\sum Y_{i+1}\right\} / n$
$\therefore \mathrm{X}_{1} \mathrm{Y}_{2} \neq \mathrm{X}_{2} \mathrm{Y}_{1}$
When $\quad X_{i}, Y_{i}$ are identical series
$\Gamma(1)=\Gamma(-1)$,
Otherewise not true.
Hence, $\Gamma_{\mathrm{ij}}(\mathrm{h})=\Gamma_{\mathrm{ij}}(-\mathrm{h})^{\boldsymbol{T}}$ proved.
Theorem 3.5: Let $X_{i}$ t's be independently and identically distributed with $E\left(X_{i t}\right)=\mu_{i}$
and $\operatorname{var}\left(X_{i t}\right)=\sigma_{i}^{2}$
then

$$
\begin{aligned}
\Gamma_{i j}(t, k) & =E\left(X_{i t}, \quad X j_{k}\right)=\sigma_{i}^{2}, \quad t=k \\
& =0, \quad t \neq k
\end{aligned}
$$

This process is stationary in the strict sense.

## Testing Procedure

Using the model for table-5.1B
$X_{i}=\left(\beta_{0}\right)_{i}+\left(\beta_{1}\right)_{i} t_{i}+\epsilon_{i}, i=1,2, \ldots 5$
Where (i) $X_{i}$ are annual temperature series $X_{i}(t), \quad i=$ 1, $2 \ldots 5$ for five districts.
(ii) $t_{i}$ are the time (in years) variable.
(iii) $\in \mathrm{i}$, are a random error term normally distributed as mean zero and variance $\sigma^{2}$, i.e $\epsilon_{i} \sim N\left(0, \sigma^{2}\right)$.
Temperature $X_{i}$ (degree centigrade) are the dependent variables and time $t_{i}$ (in years) are independent variables.

Using the model for table-5.2C and 5.3C
$\Upsilon_{i j}(h)=\left(\beta_{0}\right)_{i j}+\left(\beta_{1}\right)_{i j} h+\epsilon_{i j}, \quad i=1,2, \ldots 5 ; j=1$, $2, \ldots 5 \ldots(10)$
Where (i) $\Upsilon_{i}{ }_{j}$ (h) are auto-variance values for individual series and auto-covariance matrices for vector time series.
(ii) h are the lag values of variable.
(iii) $\epsilon_{i}$ are a random error term normally distributed as mean zero and variance $\sigma^{2}$, i.e. $\epsilon_{i} \sim N\left(0, \sigma^{2}\right) . \Upsilon_{i j}(h)$ are the dependent variables and $h$ are independent variables.
$\Upsilon_{i j}(h)$ are the dependent variables and $h$ are independent variables.

Defining $\Upsilon_{i j}(h)=\operatorname{cov}\left(X_{i}, X_{j+h}\right),(i=1,2 \ldots$ $5 ; j=1,2 \ldots 5$ ) were computed for various values of $h$ by using MS-Excel. Since the total series constituted of 33 values at least 10 values were included in the computation. The relation between $\Upsilon_{i j}(\mathrm{~h})$ and $h$ were examined the model in (table-5.2C).

Defining the $\left.\Gamma_{i j}(h)\right)=\operatorname{cov}\left(X_{i}, X_{j+h}\right)$, covariance matrix with a stationary time series for observations $\bar{X}=\left(x_{1}, x_{2}, \ldots x_{n}\right)$ realizations and $\rho_{i j}$
(h) $=$ correlation $\left(X_{i}, X_{i+h}\right)$ correlation matrix with a stationary time series for observations $\bar{X}=\left(x_{1}, x_{2}, \ldots\right.$ $x_{n}$ ) realizations, 21 such matrices corresponding to $h=0$ to 20 , define one series of matrices each $5 \times 5$, and hence 25 component series were computed. The relation between $\Gamma_{i j}(\mathrm{~h})$ and h were examined the model in (table-A1, APPENDIX-A) .

The method of testing intercept $\left(\beta_{0}\right)_{\mathrm{i} j}=0$ and regression coefficient $\left(\beta_{1}\right)_{\mathrm{ij}}=0$, [16]. Null hypothesis for test Statistic used to test and set up.
4.1: Inference concerning slope $\left(\beta_{1}\right)_{i j}$ : For testing $H_{0}:\left(\beta_{1}\right)_{i j}=0 \mathrm{Vs} H_{1}:\left(\beta_{1}\right)_{i j}>0$ for $\alpha=0.05$ percent level using $t$ distribution with degrees of freedom is equal to $n-2$ were considered.

$$
t_{n-2}=\beta_{1} / s_{\beta 1}
$$

From model, $\Gamma_{\mathrm{ij}}(\mathrm{h})=\left(\beta_{0}\right)_{\mathrm{ij}}+\left(\beta_{1}\right)_{\mathrm{ij}} \mathrm{h}+\epsilon_{\mathrm{i}}$,
Table-5.3C was obtained by regressing values of $\Gamma_{i}(\mathrm{~h})$ against h , by using this, testing shows that, both the hypothesis $\left(\beta_{0}\right)_{\mathrm{ij}}=0$ and $\left(\beta_{1}\right)_{\mathrm{ij}}=$ 0 test is not positive. (Table-A1, APPENDIX-A) formed the input for table-5.3A .

## Example of vector time series

Regional temperature data.
Here is a real instance of a vector time series. Temperature data of Marathawada region was obtained from five districts, namely Aurangabad, Parbhani, Beed, Osmanabad, and Nanded. The data were collected from "Socio Economic Review and District Statistical Abstract", Directorate of Economic and Statistics, Government of Maharastra, Bombay and "Hand Book of Basic Statistics", Maharastra State [2, 3, 4]. Hence we have five dimensional time series $t$ i , $i=1,2,3,4,5$ corresponding to the districts Aurangabad, Parbhani, Beed, Osmanabad and Nanded respectively. Table 5.1A, shows the results of descriptive statistics and Table 5.1B, shows linear trend analysis. All the linear trends were found to be not significant.

Over the years many scientists have analyzed rainfall, temperature, humidity, agricultural area, production and productivity of Marathwada region of Maharastra state, $[1,5,6,8,9,11,13,14$, 15, 18]. Most of them have treated the time series for each of the revenue districts as independent time series and tried to examine the stability or nonstability depending upon series. Most of the times non- stability has been concluded, and hence possibly any sort of different treatment was possibility never thought of. In this investigation we treat the series first and individual series and then as a vector time series shows that the vector time series are not stable.

## Conclusion

## For Individual Time Series

It was observed $t$ values are therefore not significant for the four districts i.e. $X_{i}$ does not depend on time $t$ for four districts [5]. Similarly, $\Upsilon_{i j}(\mathrm{~h})$ does not depend on $h$ in four districts except Osmanabad districts to mean that there is trend in Osmanabad districts. The testing shows that, for the hypothesis $\left(\beta_{1}\right)_{i}=0$, test is negative for time $t$ and $h$, for four districts i.e. trends were not found in four districts i.e.

## 05/INNO/ 3/2020/12181

trends were not found in four districts except Osmanabad district.

Generally it is expected, temperature (annual) over a long period at any region to be stationary time series. These results does not conform with the series in Osmanabad district.

## b) For vector time series

It is necessary to test association between $\Gamma_{\mathrm{i}}$ j (h)) and h. Conclude that a vector time series was having trend, The association between $\Gamma_{\mathrm{ij}}(\mathrm{h})$ ) and h fails in Osmanabad-0.526*individually and Osmanabad / Aurangabad -0.526*, Osmanabad / Parbhani $-0.526^{*}$ Osmanabad / Beed-0.526* and

Parbhani / Nanded $-0.526^{*}$ in combinations are seems to be causing responsible for having trend nature of the series (shown in table-5.3B) it is concluded that a vector time series found trend[16].

## Analysis: Temperature

The strategy of analyzing first individual time series as scalar series and then treating the vector series as the regional time series has been adapted here for temperature.
Temperature Time Series Treated As Scalar Time Series

Table 5.1A contains the results for scalar series approach.

## Temperature time series of five districts treated as

 a single vector time seriesTreating the series together, one may look at them as a single vector time series for the whole region, with each vector $T=\left(t_{1}, t_{2}, t_{3}, t_{4}, t_{5}\right)$ having five components. Where $t i$ is the temperature for the $\mathrm{i}^{\text {th }}$ districts.

Now for each lag value $h$ we have a $5 \times 5$ matrix $\Gamma_{i j}(\mathrm{~h})$, of auto and cross covariance values. These values, which constitute of 21 such matrices is reported in Table-5.3 Appendix-A.
Observe that,
a. the matrix $\Upsilon_{i j}(h)$ for $h=0$ is symmetric, and for $h>0$ they are not symmetric. This is expected.
b. We have a series of $5 \times 5$ matrices $\Upsilon_{i j}(h), \quad h=$ $0,1, \ldots, 20$, and now onwards we are interested in behavior of this matrix series.
c. Out of the 25 components series, 5 series showed significant (coefficients)
intercepts, and slope in table 5.3B Osmanabad$0.526^{*}$ individually and Osmanabad/Aurangabad0.526*, Osmanabad/Parbhani-0.526* Osmanabad/ Beed-0.526* and Parbhani/Nanded-0.526* in combinations are seems to be causing responsible for non-stationary nature of the series. That is both hypothesis $\beta_{0}=0$ and $\beta_{1}=0$ could be rejected. Stated in matrix terms the model (matrix equation in $5 \times 5$ matrices)
$\Gamma_{i j}(\mathrm{~h})=\beta_{\mathrm{ij}}(0)+\beta_{\mathrm{ij}}(1) \mathrm{h}+\mathrm{e}_{\mathrm{i} j}$
(h) , (i=1,2 $\ldots 5 ; j=$ 1,2 ... 5)
with hypothesis $\beta_{0}=0$ and $\beta_{1}=0$ was not validated.
Hence we can consider the vector time series to be not stationary. Thus we have a situation where the vector time series is not stationary, so the individual time series are stationary except Osmanabad districts.

Table-5.3A: Cov.( $\mathrm{h}, \Gamma_{\mathrm{ij}}(\mathrm{h})$ ) Matrix values about temperature data.

| District | Aurangabad | Parbhani | Osmanabad | Beed | Nanded |
| :--- | :---: | :---: | :---: | :---: | :---: |
| Aurangabad | -2.97 | -0.23 | 1.21 | -2.23 | -1.71 |

$t=2.1$ is the critical value for $19 \mathrm{~d} f$ at $5 \%$ L. S. * shows the significant value

## 05/INNO/ 3/2020/12181

Thus we have a situation where when treated as individual series Osmanabad is not stationary and when treated as vector time series the whole of the vector time series is not stationary. This confirms one of the properties of vector time series that

If one of the component series is non stationary, the vector series as a whole is also non stationary

When we think of the maximum temperature of whole of the region, Osmanabad individually and Osmanabad/Parbhani, Osmanabad/Beed, Osmanabad/Aurangabad, and Parbhnai/Nanded in combinations seem to be causing the variations responsible for the nonstationary nature of the series.

## Regional View of the Temperature Aspects

A regional view of the temperature aspects helps us in classifying the region into subgroups of similar temperature characteristics. From results it is clear that Aurangabad, Parbhani, Beed and Nanded are stationary in temperature time series however and Osmanabad are not so. When the vector time series is considered the region showed nonstationary behavior. This suggests that, the districts can be clustered into sub-regions which we show us homogeneous behavior. With this intention the simple analysis of variance (ANOVA) was performed. The districts are treated as a single factor and years as replicates.
5. 4A: ANOVA-table: For temperature series

| Source of variations | SS | d. f. | MS | F | P-value | F crit |
| :--- | :---: | :---: | :---: | :---: | :---: | :---: |
| Between group | 184.9 | 4.0 | 46.2 | $\mathbf{1 2 . 8}^{\boldsymbol{*}}$ | 0.0 | 2.4 |
| With in group | 579.8 | 160.0 | 3.6 |  |  |  |
| Total | 764.7 | 164.0 |  |  |  |  |

$C D=1.2$
We need only to inspect the 5 means to see any pair which differs from the CD value.

| Nanded | $=43.04$ | $=$ | $A 1$ |  |
| :--- | :--- | :--- | :--- | :--- |
| Parbhani | $=$ | 42.78 | $=$ | $\mathrm{A} 2 \Rightarrow \mathrm{~A} 1-\mathrm{A} 2=0.2$ |
| Beed | $=41.26$ | $=$ | $\mathrm{A} 3 \Rightarrow \mathrm{~A} 2-\mathrm{A} 3=1.5^{\circ}$ |  |
| Osmanabad $=$ | 40.73 | $=$ | $\mathrm{A} 4 \Rightarrow \mathrm{~A} 3-\mathrm{A} 4=0.6$ |  |
| Aurangabad $=$ | $=40.46$ | $=$ | $\mathrm{A} 5 \Rightarrow \mathrm{~A} 4-\mathrm{A} 5=0.2$ |  |

Since one result, in a difference, is greater than our CD; these two districts Parbhani and Beed differ significantly i.e. they are not at par. So we can state that these two districts are not at state value. It means that they are below the face value or may be above the face value. If we consider in terms of temperature, the Nanded $-C D=43.04-1.2=$ 41.84. It is seen that Nanded and Parbhani has greater mean values with the difference value of 41.84. So Nanded and Parbhani are at par. It means that they are at face value

Here from the ANOVA table, if $F$ is significant; it is seen that the five means are not equal. Here we have five comparisons of interest. For this, we calculate $C D$ (Critical Difference) as above. We have also arranged the means in the descending order of five districts and subtracted from CD. Therefore it is clear that Nanded and Parbhani are at par for temperature. Again we have taken corresponding difference among their respective means for the description of each temperature factor. In comparison, the temperature in Parbhani and Beed is not at par.

## Summary of temperature Result

Table 5.4B: Temperature Time Series: Summary

| Sr. | Factors | Scalar time series |  | Vector time series |
| :---: | :--- | :--- | :--- | :---: |
| No. |  | Stationary | Not stationary |  |
| 2 | temperature | Aurangabad, Parbhani, Beed, <br>  | Nanded | Osmanabad | | Not stationary at |
| :---: |

I) Time series for Aurangabad, Parbhani, Beed and Nanded are stationary i.e. not having trend.
II) Time series for Osmanabad has been unstable in temperature.
III) In weather-wise classification it is seen that Nanded and Parbhani are at par in temperature (see figure 5.1).

| Districts $\rightarrow$ <br> Factors $\downarrow$ | Nanded | Parbhani | Beed | Osmanabad | Aurangabad |
| :--- | :--- | :--- | :--- | :--- | :--- |

## Acknowledgement

The authors are thankful to Principal, Dnyanopasak College Parbhani, for providing the necessary facilities for the present investigation and encouragement. We are also grateful to Prof. H.S. Acharya, Puna College, PUNE, for his valuable guidance.
